

Ignyte × Circle × Arc · Track 4 — Agentic Economy

Subscription Autopilot

An AI agent that runs your recurring service spending on Arc — and can prove it behaved.

Agents can pay — owners can't trust them yet

Capability isn't trust. An LLM with keys in its own process is one bad input away from being someone else's wallet.

prompt_injection

one poisoned instruction and the agent overspends on command

price_drift

sellers reprice constantly — a loyal agent silently wastes money

no_audit_trail

without externally verifiable records, “the agent behaved” is just a claim

Autopilot researches, negotiates, and executes every renewal

01 · RESEARCH

Probes competing x402 sellers' live price menus — free GET /quote — against your real usage history.

02 · NEGOTIATE

Compares volume and loyalty tiers across sellers at every renewal — and switches when cheaper.

−21.9% per call, last switch

03 · EXECUTE

Gasless USDC nanopayments per call (x402), batch-settled onchain by Circle Gateway on Arc.

The agent holds zero keys; policy holds the wallet

UNTRUSTED — THE AGENT

LLM, injectable. No keys, no Circle SDK, no chain RPC. It can only ask: POST /pay with a stated reason.

CUSTODY — SPENDGUARD

allowlist → perTx → monthly →
perService → velocity → threshold

allow → pay hold → human deny → code

“The agent can want anything; it can only pay what policy allows.”

Every payment crosses one guarded path

Four core Circle products, each load-bearing

Nanopayments / x402

Core rail. Seller middleware re-resolves price per request; the `onBeforePaymentCreation` hook runs inside SpendGuard's trusted process — enforcement behind the custody wall.

Circle Wallets (DCW)

Key custody. EIP-712 signing via `signTypedData` on a developer-controlled EOA — no raw private key anywhere in the stack: payments *and* on-chain anchoring alike.

Circle Gateway

Settlement + treasury. One deposit funds the agent; every payment after is a gas-free EIP-3009 authorization, batch-settled onchain with transfer UUID receipts.

USDC on Arc

Settlement asset *and* gas token — the SpendAnchor audit transactions themselves are paid in USDC on Arc Testnet.

+ **CCTP** — autonomous cross-chain treasury top-ups (built). **USYC + StableFX** — tokenized-yield & cross-currency FX legs, wired behind feature flags and testable the moment enterprise access is granted.

The demo lands in four beats

1 Delegation

agent subscribes to the cheapest seller, meters gasless per-call payments

2 Negotiation

seller raises prices 60% → next renewal re-shops and switches, 21.9% cheaper

3 Attack

prompt-injected overspend → denied at the policy wall (per_tx_max_exceeded), human clicks Deny

4 Proof

month-end burn-down, savings from switching, denial log, receipts anchored on Arc

Verified end-to-end on Arc Testnet

- ✓ Full E2E loop cleared Day 0 — `verify-day0.sh`
- ✓ Keyless: DCW signs payments AND on-chain anchors — no raw key in the deployed stack
- ✓ All four demo beats live in production: metering, 21.9% switch, injection denied, human hold/release
- ✓ SpendAnchor DCW-owned — epochs auto-anchored every 10 min, signed keylessly (verified on-chain)

SPENDANCHOR.SOL · ARC TESTNET

0xf550a882da3c26fbacd1b68aa83867102206b143

Circle's sample shows an agent that can pay.

Autopilot pays well — cheaper, safer, gasless.
